

# Exercise set 11

TMA4160 Cryptography

4. November 2014

In the lectures we have defined a  $\Sigma$ -protocol in the following way. Let  $R = \{(h; a)\} \subseteq X \times Y$  be a binary relation, and let  $L_R = \{h \in X \mid \exists a \in Y \text{ s.t. } (h; a) \in R\}$  be the language relating to  $R$ . Then we define a  $\Sigma$ -protocol as

**Fig. 1.**  $\Sigma$ -protocol for relation  $R$ , where  $A_1$  and  $A_2$  are probabilistic polynomial time algorithms,  $C$  is a finite set and  $A_3$  is a polynomial time predicate.

**Definition 1.** A  $\Sigma$ -protocol for relation  $R$  is a protocol between a prover  $P$  and a verifier  $V$  of the form given in figure 1 satisfying the following three properties.

**Completeness.** If  $P$  and  $V$  follow the protocol, then  $V$  always accepts.

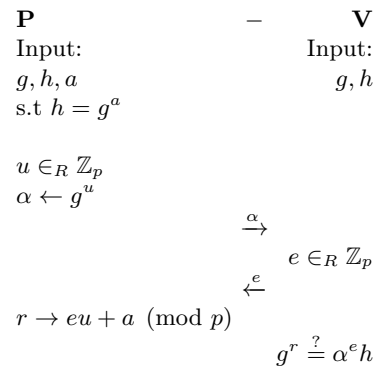

**Special soundness.** There exists a probabilistic polynomial time algorithm  $E$  which given any  $h \in X$  and any pair of accepting conversations  $(\alpha, e_1, r_1)$  and  $(\alpha, e_2, r_2)$ , with  $e_1 \neq e_2$ , computes a witness  $a$  satisfying  $(h, a) \in R$ .

**Special honest-verifier zero-knowledge.** There exists a probabilistic polynomial time algorithm  $S$  which given any  $h \in L_R$  and any challenge  $e \in C$  produces conversations  $(\alpha, e, r)$  with the same probability distribution as conversations between honest  $P$  and  $V$  on common input  $h$  and

challenge  $e$ , where  $P$  uses any witness  $a$  satisfying  $(h, a) \in R$ . Furthermore, for  $h \in X \setminus L_R$ ,  $S$  is just required to produce arbitrary accepting conversations with challenge  $e$ .

**Exercise 1**

Consider the following version of the Schnorr protocol (where we work in  $G = \langle g \rangle, |G| = p$  for prime  $p$ ):

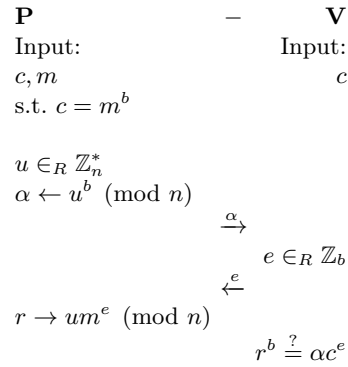

**Fig. 2.** Insecure version of Schnorr's protocol

- a) Show that this version of the Schnorr protocol is a  $\Sigma$ -protocol
- b) Show that this version of the Schnorr protocol is completely insecure against a cheating verifier, and suggest a fix.

**Exercise 2**

Let  $n = pq$  be a RSA-modulus, and  $b$  a large prime (So that  $O(b)$  is exponential in the size of  $n$ ). Consider the Guillou-Quisqater protocol for showing knowledge of  $b$ th-roots (i.e knowledge of  $m$  such that  $m^b = c$  for public  $c$ ):

**Fig. 3.** The Guillou-Quisqater protocol

Show that the Guillou-Quisqater protocol is a  $\Sigma$ -protocol

**Challenge**

**Exercise 3**

You have seen in the lectures how to use Schnorr's protocol to create a protocol for the relation  $\{(h_1, h_2; a_1, a_2) \mid h_1 = g^{a_1} \wedge h_2 = g^{a_2}\}$  (AND-protocol). Now use Guillou-Quisqater's protocol to create a protocol for the relation  $\{(c_1, c_2; m_1, m_2) \mid c_1 = m_1^b \wedge c_2 = m_2^b\}$ .
